Building Block 1: 4-6 Percent Lower Emissions from Existing Coal Generation

- EPA notes that several studies have examined the potential to improve heat rates as coal-fired power plants, noting specifically a 2009 study by the engineering firm Sargent & Lundy.
- Based on the 2009 Sargent & Lundy study, EPA estimated that potential heat rate improvements are in the order of approximately 4 to 12 percent. Furthermore, based on review of EPA and DOE EIA generation data, EPA estimates that historically EGUs have experienced heat rate improvements from 3 to 8 percent.
- Based on a review of prior studies and generation trends, EPA estimates the potential for improvements in heat rates of between 4 and 6 percent, which
